```

1.2 Analyze connectivity patterns

```

In [19]: G = nx.from_scipy_sparse_matrix(A)

```

```

In [20]: cc = nx.connected_components(G) #Fing connected components
         list_of_cc = [len(c) for c in sorted(cc, key=len, reverse=True)] #sizes of connected

```

```
In [21]: print('sizes of connected components arranged in the decrease order:')
         print(list_of_cc)
```

sizes of connected components arranged in the decrease order:

```
[1648829, 11, 8, 8, 7, 7, 7, 7, 7, 7, 6, 6, 6, 6, 6, 6, 6, 6, 6, 6, 6, 6, 5, 5, 5, 5, 5, 5,
```

1.2.1 We observe one giant connected component and many tiny components

```
In [23]: print('Number of connected components:', len(list_of_cc))
         print('Fraction of nodes in the giant connected component:', round(list_of_cc[0] / A..
```

Number of connected components: 5536

Fraction of nodes in the giant connected component: 0.993

1.2.2 Hereafter we are focused on the giant connected component

```
In [ ]: largest_cc = max(nx.connected_components(G), key=len)
         largest_cc = np.array(list(largest_cc))
         #np.save('largest_cc.npy', largest_cc)

         data = data[data.index.isin(largest_cc)]
         A = A[largest_cc, :][:, largest_cc]

         #data.to_csv('X_opinions_cc.scv', index=False)
         #sprs.save_npz('X_friends_cc.npz', A)
```

1.3 Add information on friends' opinions diversity

```
In [26]: data = pd.read_csv('X_opinions_cc.scv')
         print(data.shape[0])
         data.head()
```

1648829

7.0.1 $EPOC_+$ as a function of x_{-i} , separated by x_i . We emphasize the following regularity. For two groups G_1 and G_2 , where without loss of generality $G_1 < G_2$, it tends to hold that $EPOC_+(x_i=G_1, x_{-i}=G_2) < EPOC_+(x_i=G_2, x_{-i}=G_1)$ if G_2M and $EPOC_+(x_i=G_1, x_{-i}=G_2) > EPOC_+(x_i=G_2, x_{-i}=G_1)$ if G_1M . Exceptions here are: (1) Ls and Ms for time step t_1-t_2 ; Ms and Cs for both time steps.

8 How EPOC measures are affected by the value of $|x_{-i}(t_{k+1}) - x_{-i}(t_k)|$ (Figure C1)

9.0.1 In this plot, we demonstrate how $EPOC(t_k t_{k+1})$ is moderated by the value of σ_{-i} . Blue stars plot $EPOC_{-}(t_k t_{k+1})$ if σ_{-i} is under 0.15; purple dots plot $EPOC_{-}(t_k t_{k+1})$ if $\sigma_{-i} > 0.15$. Black stars plot $EPOC_{+}(t_k t_{k+1})$ if σ_{-i} is under 0.15; green dots plot $EPOC_{+}(t_k t_{k+1})$ if $\sigma_{-i} > 0.15$. We observe no clear trends. Perhaps, higher values of σ_{-i} are associated with a higher chance of opinion shift, but this tendency is quite weak.

10 All cross-group movements as functions of x_{-i} (Figure B1 and Figure that is not included in the main manuscript)

10.1.1 These subplots represent how the probability of a particular opinion shift depends on the average opinion of friends (here, we consider time step t_1t_2 ; the same subplots for time step t_2t_3 are included in the online supplementary materials). The dashed lines illustrate the boundaries between areas of negative (dark green), positive skipping (light green) and positive nonskipping (lime green) movements. Some subplots demonstrate that the curves do change their behavior after transitioning from the area of skipping movements to the area of nonskipping movements (see, for example, *SLC* or *SCM* whereby the curves start to grow with a higher rate after entering the nonskipping zone). However, the similar behavior (growth with an increasing rate) may be observed for movements that imply no skips (*CM*, *SCC*).

10.2 Time step $t_2 \rightarrow t_3$

15.0.1 In this plot, we demonstrate how conditional opinion shift magnitude is moderated by the value of σ_{-i} . Blue stars plot opinion shift magnitude if σ_{-i} is under 0.15; purple dots plot opinion shift magnitude if $\sigma_{-i} > 0.15$. Black stars plot opinion shift magnitude if σ_{-i} is under 0.15; green dots plot opinion shift magnitude if $\sigma_{-i} > 0.15$. We observe no clear trends.

16 The positive / negative ratio as a function of x_{-i} , control for x_i (Figure 7)
